Abstract

Objective: To assess the frequency of dietary xenoglycan Neu5Gc and antibodies in males and females and its impact on fertility.

Design: Prospective study of semen, uterine lavage, and follicular fluid from subjects undergoing infertility evaluation or in vitro fertilization (IVF) and fertile controls.

Setting: University based infertility program.

Participants: Males (n=23) and females (n=27) undergoing semen analysis and saline infusion sonography as part of their diagnostic evaluation and 37 women undergoing IVF were compared to fertile male (n=15) and female (n=14) controls.

Intervention: Neu5Gc was measured by affinity purified antibody staining on Western blots, flow cytometry, and by high performance liquid chromatography. Anti-Neu5Gc antibodies were determined by ELISA.

Main parameters measured: Frequency and levels of Neu5Gc antigen within sperm and endometrial cells and antibodies in semen, uterine lavage, and follicular fluid. Semen quality and IVF outcomes were assessed between antigen and antibody positive and negative subjects.

Results: In infertile subjects, Neu5Gc was detected in 26% of sperm and 54% of endometrial cells compared to 0% in male and 0% female controls. Anti-Neu5Gc antibodies were identified in 54% of seminal fluid, 41% in uterine lavage and 43% of follicular fluid samples. There were no differences in semen parameters, oocyte quality, and embryo development in the presence or absence of Neu5Gc antigen or antibody. However, clinical pregnancy rate was significantly lower in the presence of anti-Neu5Gc antibodies intrauterine lavage (0% vs. 54.5%, p<0.05).

Conclusions: Neu5Gc and directed antibodies are present in reproductive tracts of both male and female infertility subjects. Our results suggest their presence may interfere with fertility within the uterus environment.

Abbreviations: 1,2-diamino-4,5-methylenedioxybenzene (DMB), assisted reproductive technologies (ART), clinical pregnancy rate (CPR), cytidine monophosphate N-Acetylneuraminic acid hydroxylase (CMAH), embryo transfer (ET), high performance liquid chromatography (HPLC), in vitro fertilization (IVF), N-glycolyneuraminic Acid (Neu5Gc).

Introduction

All cell surfaces are coated by a complex array of glycans. In mammals, the majority of these surface glycans are capped with sialic acids, nine carbon backbone acidic amino sugars. By virtue of their position and high abundance at the outermost cell surface, sialic acids are involved in multiple functions including cellular recognition during development, infection and immune processes [1]. The role of sialic acids in reproduction is not fully understood, but acquisition of a
Sroga JM (2015) Detection of the dietary xenoglycan N-glycolyneuraminic acid (Neu5Gc) and anti-Neu5Gc antibodies within reproductive tracts of male and female infertility subjects

We are unaware of any information on the presence of the xenoglycan Neu5Gc and anti-Neu5Gc antibodies in the human reproductive tract or of their potential consequences on fertility. The female reproductive tract through which sperm must traverse and in which embryos must implant contains antibodies originating from plasma (IgG) and locally produced (IgA) antibodies [19]. Inflammation and the resulting abnormal milieu is a possible mechanism for impaired implantation as seen in certain disease states (i.e. endometriosis, auto-immune diseases, tubal infertility) [20,21]. It has recently been suggested, that the loss of Neu5Gc may have caused reproductive incompatibility in ancestral hominin populations due to sexual selection by female immunity against the xenoglycan Neu5Gc on sperm or implanting blastocysts [22]. In a murine model, Cmah null females with antibodies against Neu5Gc have reduced fertility when mated with Neu5Gc positive wild-type males implicating that female immunity can result in reproductive incompatibility [22].

Thus, our objectives were 1) to determine if Neu5Gc antigen and targeting antibodies are present within the human reproductive tracts of males and females; 2) to compare levels between patients seeking infertility evaluation and fertile controls; 3) to assess whether antigen or antibody presence in the reproductive tract had any impact on semen quality and in-vitro fertilzation (IVF) outcomes, and 4) to investigate if they were associated with dietary intake of foods containing the antigenic Neu5Gc xenoglycan.

**Materials and methods**

This study was reviewed and approved by the Christ Hospital Institutional Review Board (Cincinnati, OH) and the study was in compliance with privacy-act guidelines.

**Patient population**

From July 2010 to August 2014, subjects were recruited to participate in this prospective clinical study. Subjects enrolled were 1) those undergoing diagnostic infertility testing including a semen analysis (n=23) and saline infusion sonography (n=27); 2) patients undergoing in vitro fertilization (IVF) cycles (n=37, 20 of which underwent a uterine lavage after a saline infusion sonography) and 3) fertile male

(n=15) and female oocyte donors (n=14). Written informed consent was obtained from each subject candidate. Men between the ages of 18–50 years without previous vasectomy were eligible to participate.

Subjects meeting inclusion criteria were given a dietary questionnaire specifically designed for this study (Figure 1) including frequency of meat, dairy, and protein supplement intake as well as formula use as an infant, all of which contain the xenoglycan Neu5Gc. Xenoglycan load based on the questionnaire were calculated by using values from Tangvoranuntakul et al. [9].

Sample acquisition

Semenal fluid and sperm samples: Semen was collected on site in a sterile plastic specimen cup after a recommended period of abstinence of 2-5 days. The specimens were allowed to liquefy at 37°C for 30 minutes and analyzed within one hour of collection time for semen quality parameters and motion characteristics. Semen samples were then centrifuged twice for 8 minutes each time at 300 x g (1200 RPM), and the supernatant (seminal fluid) was isolated and frozen at -20°C before sample analysis. The remaining sperm pellet was reconstituted with 1-2 mL of phosphate buffered saline (PBS), then frozen at -20°C for later analysis.

Uterine samples: Saline infusion sonography was performed either during the follicular phase of a spontaneous menstrual cycle or following a progestin withdrawal bleed. Following speculum examination and cervical cleansing, a 2 lumen 5 French balloon catheter (Cooper Surgical Inc. Trumbull, CT) flushed with sterile saline was placed into the lower uterine segment followed by instillation of sterile saline through the catheter until an adequate evaluation of the uterine cavity was obtained. At completion of the saline infusion sonography, fluid was aspirated collecting both endometrial cells and saline (mean volume ~ 2 ml) for uterine lavage specimens. Uterine specimen samples were then centrifuged 15 minutes at 300 x g (1200 RPM), and the supernatant was isolated from the remaining pellet (endometrial cells). Both samples were frozen at -20°C until sample analysis.

Assisted reproduction

Ovarian stimulation-oocyte retrieval: Prior to ovulation induction for IVF, all female partners had normal uterine cavities as demonstrated on saline infusion sonography and operative hysteroscopy to correct cavity pathology.

Subjects undergoing IVF used a GnRH antagonist protocol. Briefly, ovarian stimulation was started on cycle day 3 following an oral contraceptive pill withdrawal bleed using daily injections of 150 to 300 IU of recombinant follicle stimulating hormone (rFSH) [Follistim® AQ Cartridge; Merck & Co., Inc., Whitehouse Station, NJ, USA]. All cycles were monitored by serum estradiol levels and transvaginal ultrasound and the dose was adjusted according to response. GnRH-antagonist (Ganirelix, 0.25 mg, subcutaneously daily [Merck & Co., Inc., Whitehouse Station, NJ, USA]) was begun when lead follicles were 12-14 mm. When ≥3 follicles reached 18-20 mm, urinary hCG 10,000 IU was given and was followed by transvaginal oocyte aspiration 36 hours later.

Follicular fluid and serum samples: Follicular fluid from the first dominant follicle was collected for evaluation. Follicular fluid samples were centrifuged similar to uterine lavage specimens. Granulosa cells were discarded and follicular fluid was stored at -20°C. Serum was collected around the time of hCG administration, and samples were centrifuged (same as uterine lavage), red blood cells discarded, and serum was similarly stored at -20°C until processing.

IVF-ICSI-embryo quality grading, culture, and embryo transfer: Fertilization was performed on the day of retrieval with sperm from a partner or donor using conventional IVF or intracytoplasmic sperm injection (ICSI). Three to four hours after oocyte retrieval, fertilization was performed in IVC-1 media by either conventional insemination or by ICSI in the presence of male factor infertility. The following day, fertilization was confirmed by the presence of two pronuclei. All normally fertilized embryos were cultured sequentially in Vitrolife’s G1.3 and G2.3 media, supplemented with 5% protein. An embryo transfer was performed either three or five days after oocyte retrieval under ultrasound guidance. At least 4 good quality cleavage stage embryos were required to continue culture to the blastocyst stage. Day-3 embryos were evaluated according to cell number and were graded according to blastomere uniformity and the degree of fragmentation. Day-3 embryo quality was ranked as good if >6 cells, grade 2 (slight to moderately uneven cells and slight to moderate fragmentation). Two to three embryos with the highest cell number and best morphology were selected for embryo transfer. Surplus embryos were then transferred to IVC-3 blastocyst media, which were re-evaluated on days 5 and/or 6 for development into suitable blastocysts for cryopreservation [23].

Pregnancy confirmation: Pregnancy was confirmed by serial serum β-hCG levels 7 to 10 days following embryo transfer. Clinical pregnancies were confirmed with transvaginal ultrasonography by a gestational sac at 6 to 7 weeks. Hormonal supplementation was continued until 10 weeks gestation or until a negative serum β-hCG.

Neu5Gc antigen detection: Neu5Gc was detected using an affinity purified polyclonal IgY antibody raised in chickens[24]. Frozen sperm were thawed and washed 3X with PBS. For flow cytometry, thawed sperm were first blocked with 0.5% fish gelatin in PBS (PBSfG) for 30 min at RT, then incubated with anti-Neu5Gc IgY at 1:1000 in PBSfG for 30 min on ice, washed 3 times with PBSfG, incubated with secondary donkey-anti chicken Dy488 at 1:1000 in PBSfG for 30 min on ice, washed 3X with PBSfG and measured on a FACScalibur Flow cytometer. Controls included: mild periodate treatment (2mM NaIO4), which truncates the side chain of sialic acid and confirms sialic acid dependence of Ab staining; inhibition of the Ab with 10 mM polyNeu5Gc, and non-specific isotype control.

Human sperm Neu5Gc detection via Western Blot

Frozen sperm samples from control fertile males were thawed and centrifuged (500 g, 5 minutes). The supernatant, containing seminal fluid, was aspirated, followed by two washing cycles characterized by addition of 1 mL of phosphate buffered saline (PBS), centrifugation (500 g, 5 minutes), and aspiration of the supernatant. The remaining pellet was resuspended in 100 ul of PBS. Protein concentration was determined by BCA, then an equal amount of protein (18 or 30 ug per lane) was loaded on a 1.5 mm 7% SDS-PAGE gel and run until the dye front almost ran off the gel (20 minutes at 20 mamps per gel, 60-80 minutes at 40 mamps per gel). Gels were washed with milliQ water, then transferred onto a polyvinylidene fluoride (PVDF) membrane using a Bio-Rad SemiDry Transfer Cell for 1 hour (100 mamps per membrane). Membranes were washed (5 minutes) in PBS-T (0.1% Tween), blocked for one hour at room temperature in 0.5% fish gelatin PBS-T. Membranes were then incubated in PBS-T with 1:10,000 anti-Neu5Gc chicken IgY overnight at 4°C. Membranes were washed four times (7 minutes in PBS-T), followed by a secondary incubation in PBS-T with 1:10,000 LiCOR donkey a-chicken 800 antibody for 45 minutes at room temperature. Membranes were washed four more
Detection of Neu5Gc Antigen and Anti-Neu5Gc Antibodies

Semen and sperm samples: Neu5Gc was identified in 26% (6/23) of sperm samples from males undergoing fertility evaluation compared to 0/15 male controls, p<0.05. Anti-Neu5Gc antibodies in males undergoing fertility evaluation were detected in 54% of SF (8/13; insufficient sample in 10 patients). Specifically, 54% had IgA Abs detected, 38% had IgG and 38% IgM, respectively. Antibodies were not measured in fertile male controls. (Figure 2 and Table 1).

Uterine lavage, follicular fluid, and serum: The presence of Neu5Gc in endometrial cells from female infertility patients was detected in 54% (9/17; insufficient sample in 10 patients). Neu5Gc was not measured in fertile female controls. Anti-Neu5Gc antibodies were detected in 41% of uterine lavage (11/27) from female infertility patients (specifically, 37% IgA, 27% IgG, and 0% IgM) compared to none of the female controls (0%, 0/14, p<0.05) Anti-Neu5Gc antibodies were detected in 43% of follicular fluid (16/37), and 44% of serum ([14/32]; insufficient sample in 5 patients) (Table 2). Of the follicular fluid samples, 22% had IgA, 32% IgG, and 19% IgM while in serum samples, 33% had IgA, 60% IgG, and 0% IgM, respectively. Neu5Gc antibodies in follicular fluid and serum were not measured in fertile

Clinical outcomes in fertility patients

Outcomes measured included 1) The frequency of Neu5Gc Antigen in semen samples and EC and Neu5Gc antibody in seminal fluid, uterine lavage and follicular fluid; 2) The effect of Neu5Gc antigen or anti- Neu5Gc antibodies on semen parameters (semen quality including volume, concentration, motility, and strict morphology) and IVF outcomes (i.e. number of retrieved oocytes, fertilized embryos, embryo quality, rates of blastulation, pregnancy rate (PR) and clinical pregnancy rate (CPR). Analyses were also performed to correlate Neu5Gc antigen or anti- Neu5Gc antibody presence in reproductive tissue with dietary intake.

Statistics

Statistical analyses were performed using the Statistical Package for the Social Sciences (SPSS version 18; SPSS, Inc., Chicago, IL). Student’s t-test was utilized to compare means for parametric data between Neu5Gc Ag and Ab positive and negative subjects. Chi-square was used for categorical comparisons. Pearson correlation was used for correlation analysis. Significance was assessed at p<0.05. Means expressed as ±SEM.

Results

Detection of Neu5Gc Antigen and Anti-Neu5Gc Antibodies

Semen and sperm samples: Neu5Gc was identified in 26% (6/23) of sperm samples from males undergoing fertility evaluation compared to 0/15 male controls, p<0.05. Anti-Neu5Gc antibodies in males undergoing fertility evaluation were detected in 54% of SF (8/13; insufficient sample in 10 patients). Specifically, 54% had IgA Abs detected, 38% had IgG and 38% IgM, respectively. Antibodies were not measured in fertile male controls. (Figure 2 and Table 1).

Uterine lavage, follicular fluid, and serum: The presence of Neu5Gc in endometrial cells from female infertility patients was detected in 54% (9/17; insufficient sample in 10 patients). Neu5Gc was not measured in fertile female controls. Anti-Neu5Gc antibodies were detected in 41% of uterine lavage (11/27) from female infertility patients (specifically, 37% IgA, 27% IgG, and 0% IgM) compared to none of the female controls (0%, 0/14, p<0.05) Anti-Neu5Gc antibodies were detected in 43% of follicular fluid (16/37), and 44% of serum ([14/32]; insufficient sample in 5 patients) (Table 2). Of the follicular fluid samples, 22% had IgA, 32% IgG, and 19% IgM while in serum samples, 33% had IgA, 60% IgG, and 0% IgM, respectively. Neu5Gc antibodies in follicular fluid and serum were not measured in fertile

Sroga JM (2015) Detection of the dietary xenoglycan N-glycolylneuraminic acid (Neu5Gc) and anti-Neu5Gc antibodies within reproductive tracts of male and female infertility subjects

Volume 1(3): 72-78

Dietary intake and correlation between serum and reproductive fluids: No positive correlation was noted between dietary intake of red meat, dairy products nor infant formula use and Neu5Gc or anti-Neu5Gc antibody status in any reproductive fluid or serum. The presence of any serum anti-Neu5Gc antibody positively correlated to antibody presence within follicular fluid (r=0.58, p<0.001).

Discussion

To our knowledge this study is the first to explore the frequency of incorporation of non-human xenoglycan Neu5Gc sialic acid and the potential role of Neu5Gc and targeting antibody in male and female infertility subjects. Our data demonstrate that Neu5Gc and targeting antibody are abundantly expressed within both the male and female reproductive tracts of infertility subjects. Our preliminary results also suggest that the presence of the Neu5Gc xenoantigen or anti-Neu5Gc antibodies do not adversely impact sperm parameters or ovarian function including oocyte development and embryo quality. However, the presence within the uterine environment may possibly impact implantation and pregnancy outcomes.

¹Insufficient follicular fluid sample in 5 patients

Female controls.

Demographics

Male Subjects: Demographics including age (30.5 ± 3.5 years vs. 32.2 ± 5.8 years) or BMI (27.3 ± 5.7 kg/m² vs. 28.7 ± 6.5 kg/m²), p-NS) were similar between patients that were positive or negative for Neu5Gc antigen on sperm or targeting antibodies within SF (Table 3) and controls (31.4 ± 8.5 years and 25.3 ± 4.7 kg/m²).

Female subjects: Age (36.8 ± 6.9 years vs. 33.0 ± 5.7 years), BMI (29.1 ± 5.7 kg/m² vs. 26.5 ± 8.3 kg/m², p-NS) or primary infertility diagnosis (data not shown) was not different between patients that were positive or negative for anti-Neu5Gc antibodies in uterine or ovarian environments (Table 3). While controls were significantly younger (27.7 ± 2.9 years, p<0.05), BMI was similar (25.2 ± 4.7 kg/m²) to study subjects. Subjects who were positive for any antibody type (IgA, or IgG) within the uterine lavage had a lower gravidity (1.5 ± 1.7 vs. 2.9 ± 1.8, p<0.05) and parity (0.2 ± 0.4 vs. 1.3 ± 1.5, p<0.05) when compared to antibody negative subjects but not to controls (1.4 ± 0.4 and 1.3 ± 0.4, p-NS). No difference was seen in any demographic parameter and antibody presence within follicular fluid subjects undergoing IVF cycles.

Diagnostic testing and clinical outcomes

Semen analysis and saline infusion sonography: Overall, the presence of Neu5Gc antigen or anti-Neu5Gc antibodies did not correlate with differences in semen quality or the presence of uterine pathology. Specifically, semen volume (3.0 ml vs. 2.7 ml), total sperm concentration (55.7 ± 10^6 vs. 42.1 ± 10^6), motility (54.2% vs. 57.9%) and morphology (5.5% vs 6.4%) and intrauterine pathology identified on saline infusion sonography (18% vs 38%) were similar regardless of Neu5Gc antigen or anti-Neu5Gc antibody status (Table 3).

Follicular fluid, uterine lavage and IVF outcomes: In those undergoing IVF, the total number of retrieved oocytes (10.7 ± 5.5 vs. 11 ± 5.9, p-NS) and Metaphase II oocytes (8.1 ± 4.2 vs. 8.1 ± 4.0, p-NS) were similar regardless of detectable anti-Neu5Gc antibodies within follicular fluid of infertility patients. There were no adverse effects of anti-Neu5Gc antibodies on high quality embryos and rates of blastulation (data not shown). PR and CPR of these 37 subjects were similar in follicular fluid anti-Neu5Gc antibody positive or negative patients, respectively (25.0% vs. 23.8%, p-NS) and CPR (18.8% vs. 23.8%, p-NS).

Analysis was done on 20 of 37 IVF subjects who had uterine lavage with known Neu5Gc antigen and antibody status, The CPR per patient was significantly lower in those who were positive for any antibody (0% vs. 54.5%, p<0.05) and specifically for IgG antibody (0% vs. 50%, p<0.05), though not different in the presence or absence of IgA antibody (0% vs. 42.8%, p=0.08). CPR per cycle (fresh and frozen combined cycles, n=27) was lower in the presence of any antibody (0% vs 50%, p<0.01), IgA antibody (0% vs 31.4%, p<0.01); and IgG antibody (0% vs 46.1%, p<0.05) when compared to antibody negative subjects (Figures 3 and 4).

¹Insufficient follicular fluid sample in 5 patients
Detection of the dietary xenoglycan N-glycolylneuraminic acid (Neu5Gc) and anti-Neu5Gc antibodies within reproductive tracts of male and female infertility subjects

The presence of Neu5Gc antigen or anti-Neu5Gc antibodies is not surprising as other investigators have reported the presence of this xenoglycan and associated antibodies in both normal and diseased human tissues [9,10]. With respect to fertility, it has been suggested that antibodies within the uterine environment may impair fertility by two potential mechanisms including sperm inactivation and embryo rejection or failed implantation secondary to incompatibility between the blastocyst and receptive uterus [22]. Our results reveal a lower CPR in the presence of anti-Neu5Gc antibodies within the uterine environment. Moreover, none of the women positive for anti-Neu5Gc IgG antibodies achieved pregnancy even with repeat embryo transfer. In light of our study subjects undergoing IVF and the production of HQ embryos, it would suggest that implantation may be negatively affected in the presence of anti-Neu5Gc antibodies, contributing to infertility in these subjects.

The unique human sialic acids biology has brought about a situation where a dietary molecule can get incorporated into healthy human tissues and become a xeno-auto-antigen. The presence of the xeno-auto-antigen Neu5Gc in human reproductive tracts, cells, and secretions could contribute to anti-glycan immune related impaired fertility (xenosialitis affecting fertility). The presence of a non-self glycan (Neu5Gc) at the molecular frontier of the embryo, combined with antibodies targeting this molecule is consistent with our observed adverse effects on implantation success.

The fact that we found no consistent correlations between the dietary factors and antigen or antibody status is not surprising. The accumulation of xenoglycan Neu5Gc is highly variable between individuals and between tissues within individuals [9]. Additionally, dietary intake over a lifetime is challenging to assess accurately and would require very strong associations to detect significant correlations with our current intake assessment methodology. For future studies to better address the relationship between dietary load of xenoglycans and the biological consequences, extensive resources will need to be devoted to either collecting dietary intake prospectively over long periods of time or developing detailed recall questionnaires specifically targeting dietary sources of Neu5Gc.

Our study demonstrates that Neu5Gc and targeting antibody are abundant within the human reproductive tract. To our knowledge, this is the first study to evaluate the role of this xenoglycan and targeting antibodies within human fertility. However, there are a number of limitations including: 1) small sample size which was not powered to detect clinical outcomes; 2) fluids collected were not all from same cohort (semen-uterine lavage-follicular fluid-serum); and 3) the precise localization of Neu5Gc antigen in the uterus could not be established beyond its presence on shed epithelial cells recovered from the uterine lavage.

Future studies will focus on elucidating the potential functional deficits of sperm bearing Neu5Gc and targeting antibodies and...
evaluating the males and females within the same couple in order to better understand the role of Neu5Gc and targeting antibodies in subfertile or infertile couples. Such investigations will reveal to what extent xenosialitis, the contribution of the xenoglycan Neu5Gc to heightened or chronic inflammation, also affects human reproduction [18] and will point to potential mechanisms involved.

Acknowledgments

Authors would like to thank Dr. Michael Thomas and Dr. Krystene DiPaola at the University of Cincinnati for patient referral for participation and the G. Harold and Leila Y. Mathers Foundation for funding for the Gagneux laboratory.
